PAPER 2 (SECTION A)

Question		Answer	Mark
A1	ai	potassium and chlorine	1
	aii	chlorine	1
	aiii	copper	1
	aiv	aluminium	1
	av	potassium and chlorine	1
	b	True, False, True, True	3
A2	a	Petroleum is <u>heated</u> and <u>vapourised</u> in a furnace before it enters the fractionating column.	1
		The vapours consist of <u>different fractions</u> , which have <u>different boiling points</u> .	1
		The fractionating column is cooler at the top than at the bottom. As the vapours rise up the column, they will <u>cool and condense</u> . Each fractions will <u>condense at different temperatures</u> .	1
	b	The <u>smaller hydrocarbon</u> , propane, has a <u>lower boiling point</u> will be distilled and collected at the <u>top</u> of the fractionating column while the bigger hydrocarbon, octane, has a <u>higher boiling point</u> and will be collected <u>lower</u> in fractionating column.	1
		Propane and butane are of similar sizes and have very <u>similar boiling points</u> .	1

	c	compound propane octane	molecular formula $\underline{\text{C}_3\text{H}_8}$ C_8H_{18}	empirical formula $\underline{\text{C}_3\text{H}_8}$ $\underline{\text{C}_4\text{H}_9}$	2
	di	Octane has a <u>greater number of carbon and hydrogen atoms</u> than butane. More carbon dioxide and water are <u>formed</u> in the <u>combustion of octane</u> than butane, hence <u>more energy is released</u> in <u>forming</u> of the <u>bonds</u> in <u>water</u> and <u>carbon dioxide</u> than <u>absorbed</u> in <u>breaking</u> the <u>bonds</u> in <u>octane</u> and <u>oxygen</u> . <u>Energy is released in forming 8 more moles of carbon dioxide and 8 more moles of water in octane than butane. The This more than the energy absorbed in the breaking of bonds in the alkanes and oxygen.</u>			1 1
	dii	number of moles of 50 kg octane = $50000 / 114 = 438.60 \text{ mol}$ total energy released from 50kg of octane = $438.60 \times 5470 = 2399122 \text{ kJ}$ number of moles of butane required to produce energy = $2399122 / 2880 = 833.03 \text{ mol}$ mass of butane required = $833.03 \times 58 = 48300 \text{ g} = 48.3 \text{ kg}$			1 1 1
A3	a	1: hydrogen, oxygen 2: hydrogen, chlorine 4: copper, copper(II) ions			2
	b	In experiments 1 and 2, <u>carbon electrodes</u> that were <u>inert</u> were used at the <u>positive electrodes</u> . This allowed <u>anions</u> in the solutions to be <u>preferentially discharged</u> and <u>oxidised</u> , forming substances like oxygen and chlorine. In experiment 4, <u>copper electrodes</u> that were <u>not inert</u> were used at the <u>positive electrode</u> . This caused the <u>copper electrode</u> to <u>oxidise</u> , forming <u>copper(II) ions</u> .			1 1
	ci	<u>Reddish brown solid</u> is <u>deposited</u> on the negative electrode.			1
	cii	$4\text{OH}(\text{aq}) \rightarrow \text{O}_2(\text{g}) + 2\text{H}_2\text{O}(\text{l}) + 4\text{e}^-$			1
	ciii	<u>Blue solution turns colourless</u> . The <u>copper(II) ions</u> were <u>preferentially discharged</u> at the <u>negative electrode</u> and concentration of <u>copper(II) ions</u> <u>decreases</u> .			1 1
A4	a	calcium silicate			1

		CaSiO ₃	
	bi	Maximum mass of iron = $112 / 160 \times 14000 = 9800$ tonnes	3
	bii	Iron ore is a <u>mixture</u> containing <u>iron(III) oxide</u> mixed with <u>impurities</u> like sand and clay. <u>Solid iron(III) oxide</u> cannot be <u>reduced completely</u> with carbon monoxide. <u>Iron</u> could be oxidised back to <u>iron(III) oxide</u> due to presence of oxygen and high temperatures in the blast furnace. <i>Any 2 of the above.</i>	1 1
	c	Nitrogen is present from the <u>hot air</u> used to provide oxygen to react with coke. Carbon dioxide is formed from coke reacting with oxygen in the hot air and <u>decomposition of limestone</u> . Carbon monoxide is formed from the <u>reaction</u> between <u>carbon dioxide</u> with coke.	1 1 1
	d	Pure iron is soft and adding carbon will form the alloy steel, which is <u>stronger and harder</u> . Carbon added is of a <u>different atomic size from iron</u> and it <u>disrupts the orderly arrangement of the layers of iron atoms</u> . It is <u>more difficult for the layers</u> of atoms to <u>slide over one another</u> . Amounts of carbon added is carefully controlled as higher amounts of carbon will make steel brittle.	1 1
A5	a	 1m: bonding electrons between N and H 1m: bonding electrons between N and C + C and O 1m: non-bonding electrons	3
	bi	At a high temperature, the <u>aqueous solution</u> of DEF will react with water vapour to <u>form the gases</u> , NH ₃ and CO ₂ . As gases occupy a greater volume than liquids, this <u>increases the pressure</u> in the tank.	1
	bii	<u>Ammonia</u> produced from DEF can <u>remove oxides of nitrogen</u> , NO and NO ₂ , from the exhaust gas, <u>reducing acid rain formation</u> which would otherwise <u>harm aquatic life and plants</u> . <u>Removing oxides of nitrogen</u> would (decrease photochemical smog and) also <u>reduce respiratory difficulties</u> .	1 1

	biii	The DEF does not remove carbon dioxide from the exhaust gas. Carbon dioxide produced <u>traps excess heat in the atmosphere</u> which causes <u>global warming</u> . Global warming causes <u>ice bergs at the poles to melt</u> , <u>sea level to rise</u> and leading to <u>floods in lowlands</u> .	1 1
	biv	$4(\text{NH}_2)_2\text{CO} + 6\text{NO}_2 \rightarrow 7\text{N}_2 + 8\text{H}_2\text{O} + 4\text{CO}_2$	2
	c	number of moles of urea = $160 / 60 = 2.6667 \text{ mol}$ concentration of urea = $2.6667 / 0.500 = 5.33 \text{ mol/dm}^3$	1 1

PAPER 2 (SECTION B)

Question		Answer	Mark
B6	ai	Hydrochloric acid and ethanoic acid fit the general formula, HA. As hydrogen ion has the formula of H^+ , the formula of the anion would be A^- . Hence, <u>Cl^- and CH_3COO^- in hydrochloric acid and ethanoic acid</u> can be represented by <u>A^-</u> . <u>Sulfuric acid does not fit</u> the general formula as the sulfate ion has a formula of <u>SO_4^{2-}</u> and the charge on A^- is incorrect.	1 1
	aii	$2\text{HA} + \text{M}_2\text{CO}_3 \rightarrow \text{CO}_2 + \text{H}_2\text{O} + 2\text{MA}$	1
	aiii	$2\text{CH}_3\text{COOH} + \text{Ca} \rightarrow (\text{CH}_3\text{COO})_2\text{Ca} + \text{H}_2$ As the positive charge on calcium is $2+$, $x = 2$ when $x = 2$, Equation 2 will be $2\text{HA} + \text{M} \rightarrow \text{MA}_2 + \text{H}_2$	1 1
	bi	The relationship shows that <u>the initial concentration of the acid is inversely proportional to the pH</u> , which is <u>incorrect</u> . It is expected for pH of different acids to be the same when initial concentrations of the acids are the same. <u>Hydrochloric acid, sulfuric acid and ethanoic acid</u> at the same concentration of <u>0.01 mol/dm^3</u> have a pH of <u>2.0, 1.7</u> and <u>3.4</u> respectively, showing that there are other factors that affect pH of an acid.	1 1
	bii	The <u>strength of the acid</u> affects the pH of the acid. <u>Hydrochloric acid</u> is a <u>strong monobasic acid</u> , while <u>ethanoic acid</u> is a <u>weak monobasic acid</u> . At acid concentration of 0.01 mol/dm^3 , the complete dissociation of <u>hydrochloric acid</u> produces a <u>higher concentration of hydrogen ions</u> (0.01 mol/dm^3) than the partial dissociation of ethanoic acid (0.0004 mol/dm^3) and a <u>lower pH</u> . The <u>basicity of the acid</u> also affects the pH of the acid. <u>Sulfuric acid</u> is a <u>strong dibasic acid</u> , while <u>hydrochloric acid</u> is a <u>strong monobasic acid</u> . At acid concentration of 0.01 mol/dm^3 , the complete dissociation of <u>sulfuric acid</u> (0.02 mol/dm^3) produces <u>double the concentration of hydrogen ions</u> compared to the complete dissociation of hydrochloric acid (0.01 mol/dm^3) and a <u>lower pH</u> .	3
	2020 Answer	<i>1m strength, 1m basicity, 1m higher concentration + lower pH</i>	4

	bii	0.04, 1.4	1
	i	0.10, 1.0	1
B7	ai	$\text{—O—(CH}_2\text{)}_4\text{—O—}\overset{\text{O}}{\parallel}\text{C—(C}_6\text{H}_4\text{)—}\overset{\text{O}}{\parallel}\text{C—}$ Relative molecular mass of repeating unit = 16 + 4(14) + 16 + 28 + 76 + 28 = 220	2
	aii	$\begin{array}{ccccccc} & \text{O} & \text{H} & \text{H} & \text{O} & & \\ & \parallel & & & \parallel & & \\ \text{H} & \text{—O—C—} & \text{C—} & \text{C—} & \text{C—O—} & \text{H} & \\ & & & & & & \\ & & \text{H} & \text{H} & & & \end{array}$	2
	bi	There are <u>ester linkages</u> joining the monomers together.	1
	bii	Both polymerisation processes involve <u>only one type of monomer</u> . Condensation polymerisation of molecule C <u>eliminates a simple molecule like water</u> while addition polymerisation of ethene <u>does not eliminate any molecule</u> . Condensation polymerisation of molecule C involves <u>monomers with functional groups at each end of the molecule</u> while addition polymerisation of ethene involves <u>unsaturated monomers</u> .	1 1 1
EIT	a	<u>Aluminium is the most reactive, followed by carbon and silicon.</u> Carbon is more reactive than silicon as <u>silicon dioxide can be reduced by carbon</u> . Aluminium is more reactive than carbon as <u>aluminium oxide cannot be reduced by carbon</u> .	1 1
B8	b	Aluminium oxide has a <u>giant ionic structure</u> with <u>strong ionic bonds between oppositely charged ions</u> . A <u>large amount of energy</u> is needed to <u>overcome the strong ionic bonds</u> in aluminium oxide and it has a <u>high melting and boiling point</u> and exists as a <u>solid with high density</u> . In <u>molten</u> state, the giant ionic structure collapse and the <u>ions are free to move</u> to conduct electricity. Silicon dioxide has a <u>giant molecular structure</u> with an extensive network of <u>strong covalent bonds between the atoms</u> . A <u>large amount of energy</u> is needed to <u>overcome the strong covalent bonds</u> in silicon dioxide and it has a <u>high melting and boiling point</u> and exists as a <u>solid with high density</u> . Carbon monoxide has a <u>simple molecular structure</u> with <u>weak intermolecular forces of attraction</u> between the molecules. A <u>low amount of energy</u> is needed to <u>overcome the weak intermolecular forces of attraction</u> in carbon monoxide and it has a <u>low melting and boiling point</u> and exists as a <u>gas with low density</u> . Silicon dioxide and carbon monoxide have <u>no mobile charged particles</u> available to conduct electricity.	1 1 1 1 1

	c	Mass of aluminium = $2.8 \times 27 = 75.6 \text{ g}$ Percentage by mass of aluminium = $75.6 / 100 \times 100\% = 75.6 \%$ In alloy Y, percentage by mass of silicon = $100 - 75.6 - 8 = 16.4 \%$ Hence, the alloy is Y.	1 1 1
OR B8	a	<u>Experiment 2.</u> Comparing experiment 2 to experiment 1, only the <u>concentration of iodide ions</u> used is <u>changed</u> while other conditions are constant. Comparing experiment 2 to experiment 3, only the <u>temperature</u> used is <u>changed</u> while other conditions are constant. Comparing experiment 2 to experiment 4, only the <u>presence of catalyst</u> added is <u>changed</u> while other conditions are constant.	1 1
	b	When concentration increases from 0.1 mol/dm^3 to 0.2 mol/dm^3 , there are <u>more iodide ions per unit volume</u> . Hence, there are <u>more collisions</u> between the reactant particles, leading to a <u>higher frequency of effective collisions</u> , resulting in a <u>faster rate of reaction</u> , and decreasing time taken for blue-black colour to appear.	1
		When temperature increases from 20°C to 40°C , reactant particles have <u>more heat energy</u> and hence higher kinetic energy. They <u>move faster</u> and there are <u>more collisions</u> between the reactant particles, leading to a <u>higher frequency of effective collisions</u> , resulting in a <u>faster rate of reaction</u> , and decreasing time taken for blue-black colour to appear.	2
		When Cu^{2+} ions were added, they provide an <u>alternative pathway of lower activation energy</u> for the reaction to proceed. <u>More iodide ions</u> have the <u>lower minimum activation energy</u> for <u>higher frequency of effective collisions</u> to take place, resulting in a <u>faster rate of reaction</u> and decreasing time taken for blue-black colour to appear.	2
	c	number of moles of hydrogen peroxide = $0.03 \times 0.05 = 0.0015 \text{ mol}$ number of moles of aqueous iodide ions in experiment 1 = $0.1 \times 0.01 = 0.0010 \text{ mol}$ <u>0.0010 mol of aqueous iodide ions requires 0.0005 mol of hydrogen peroxide to react.</u> Hence, the <u>aqueous iodide ion</u> is the <u>limiting reactant in experiment 1</u> . number of moles of aqueous iodide ions in experiments 2, 3 and 4 = $0.2 \times 0.01 = 0.0020 \text{ mol}$ <u>0.0020 mol of aqueous iodide ions requires 0.0010 mol of hydrogen peroxide to react.</u> Hence, the <u>aqueous iodide ion</u> is also the <u>limiting reactant in experiments 2, 3 and 4</u> .	1 1 1
